

## Stacks

1

## Example: Algorithm on an Example Expression

2

## Overview and Reading

- ◆ Reading: Chapter 5.1
- ◆ Last-In-First-Out Data Structure

Input sequence 1, 2, 3, 4 ≠ Output sequence 4, 3, 2, 1

3

## The Stack ADT

- ◆ The **Stack** ADT stores arbitrary objects
- ◆ Insertions and deletions follow the last-in first-out scheme
- ◆ Think of a spring-loaded plate dispenser
- ◆ Main stack operations:
  - **push(object)**: inserts an element
  - **object pop()**: removes the last inserted element
- ◆ Auxiliary stack operations:
  - **object top()**: returns the last inserted element without removing it
  - **integer size()**: returns the number of elements stored
  - **boolean empty()**: indicates whether no elements are stored

4

## Stack Interface in C++

- ❑ C++ interface corresponding to our Stack ADT
- ❑ Uses an exception class `StackEmpty`
- ❑ Different from the built-in C++ STL class `stack`
- ❑ STL: Standard Template Library

```
template <typename E>
class Stack {
public:
    int size() const;
    bool empty() const;
    const E& top() const
        throw(StackEmpty);
    void push(const E& e);
    void pop() throw(StackEmpty);
}
```

5

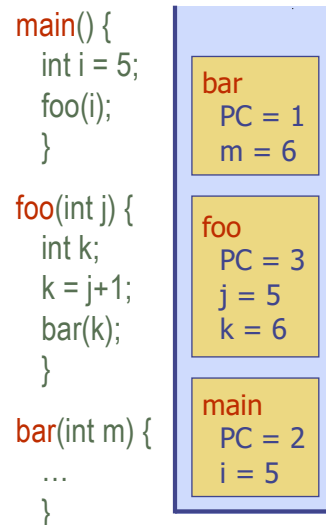

## Applications of Stacks

- ❑ Direct applications
  - Page-visited history in a Web browser
  - Undo sequence in a text editor
  - Chain of method calls in the C++ run-time system
- ❑ Indirect applications
  - Auxiliary data structure for algorithms
  - Component of other data structures

6

## Example: C++ Run-Time Stack

- ❑ The C++ run-time system keeps track of the chain of active functions with a stack
- ❑ When a function is called, the system pushes on the stack a frame containing
  - Local variables and return value
  - Program counter, keeping track of the statement being executed
- ❑ When the function ends, its frame is popped from the stack and control is passed to the function on top of the stack
- ❑ Allows for recursion
- ❑ PC: Program Counter

7

## Example Implementation: Array-based Stack

- ◆ A simple way of implementing the Stack ADT uses an array
- ◆ We add elements from left to right
- ◆ A variable keeps track of the index of the top element

8

## Example Implementation: Array-based Stack

- ◆ A simple way of implementing the Stack ADT
- ◆ Add elements from left to right
- ◆ A variable keeps track of the index of the top element
- ◆ The array storing the stack elements may become full
  - A push operation will then throw a `StackFull` exception
  - Limitation of the array-based implementation
  - Not intrinsic to the Stack ADT

```

Algorithm size():
    return t + 1
Algorithm empty():
    return (t < 0)
Algorithm top():
    if empty() then
        throw StackEmpty exception
    return S[t]
Algorithm push(e):
    if size() = N then
        throw StackFull exception
    t ← t + 1
    S[t] ← e
Algorithm pop():
    if empty() then
        throw StackEmpty exception
    t ← t - 1
    
```

9

## Performance and Limitations

- ◆ Performance
  - Let  $n$  be the number of elements in the stack
  - The space used is  $O(n)$
  - Each operation runs in time  $O(1)$
- ◆ Limitations
  - The maximum size of the stack must be defined a priori and cannot be changed
  - Trying to push a new element into a full stack causes an implementation-specific exception
- ◆ Linked-list based Stack in the text (Chapter 5.1.5)

10

## Array-based Stack in C++

```

template <typename E>
class ArrayStack {
private:
    E* S; // array holding the stack
    int cap; // capacity
    int t; // index of top element
public:
    // constructor given capacity
    ArrayStack(int c) :
        S(new E[c]), cap(c), t(-1) {}
    
```

```

void pop() {
    if (empty()) throw StackEmpty
        ("Pop from empty stack");
    t--;
}
void push(const E& e) {
    if (size() == cap) throw
        StackFull("Push to full stack");
    S[++ t] = e;
}
... (other methods of Stack interface)
    
```

11

## Example use in C++

```

ArrayStack<int> A; // A = [], size = 0
A.push(7); // A = [7*], size = 1
A.push(13); // A = [7, 13*], size = 2
cout << A.top() << endl; A.pop(); // A = [7*], outputs: 13
A.push(9); // A = [7, 9*], size = 2
cout << A.top() << endl; // A = [7, 9*], outputs: 9
cout << A.top() << endl; A.pop(); // A = [7*], outputs: 9
ArrayStack<string> B(10); // B = [], size = 0
B.push("Bob"); // B = [Bob*], size = 1
B.push("Alice"); // B = [Bob, Alice*], size = 2
cout << B.top() << endl; B.pop(); // B = [Bob*], outputs: Alice
B.push("Eve"); // B = [Bob, Eve*], size = 2
    
```

\* indicates top

12

## Stack in C++ STL

```
#include <stack>
using std::stack;           // make stack accessible
stack<int> myStack;         // a stack of integers
```

`size()`: Return the number of elements in the stack.

`empty()`: Return true if the stack is empty and false otherwise.

`push(e)`: Push *e* onto the top of the stack.

`pop()`: Pop the element at the top of the stack.

`top()`: Return a reference to the element at the top of the stack.

13

## Example: Parentheses Matching

□ Each “(”, “{”, or “[” must be paired with a matching “)”, “}”, or “]”

- correct: ( ) ( ( ) ) { [ ( ) ] }
- correct: ( ( ( ) ( ) ) { [ ( ) ] }
- incorrect: ) ( ( ) ) { [ ( ) ] }
- incorrect: ( { [ ] }
- incorrect: (

◆ Good Programmer

- Someone who thinks that stack is a good data structure for the above task

14

## Example: Computing Spans

□ Given an array  $X$ , the **span**  $S[i]$  of  $X[i]$  is the maximum number of consecutive elements  $X[j]$  immediately preceding  $X[i]$  and such that  $X[j] \leq X[i]$

□ Spans have applications to financial analysis

- E.g., stock at 52-week high

$X$	6	3	4	5	2
$S$	1	1	2	3	1

15

## Algorithm: span1

	$i$				
$X$	6	3	4	5	2
$S$	1	1	2	3	1

◆ Loop over  $i = 0, 1, 2, 3, 4$

◆ For each  $i$ , compute  $S[i]$ . How?

- From  $X[i]$  downward on, compute the number of elements which are consecutively smaller than  $X[i]$

16

## Quadratic Algorithm

### Algorithm *spans1(X, n)*

**Input** array  $X$  of  $n$  integers

**Output** array  $S$  of spans of  $X$

$S \leftarrow$  new array of  $n$  integers

**for**  $i \leftarrow 0$  **to**  $n - 1$  **do**

$s \leftarrow 1$

**while**  $s \leq i \wedge X[i - s] \leq X[i]$

$s \leftarrow s + 1$

$S[i] \leftarrow s$

**return**  $S$

#

$n$

$n$

$n$

$1 + 2 + \dots + (n - 1)$

$1 + 2 + \dots + (n - 1)$

$n$

1

◆ Algorithm *spans1* runs in  $O(n^2)$  time

17

## Algorithm: span2

From index 3 to 1, from index 4, from index 0. The consecutive largest. So, please check  $X[0]$  after it.

Stack for "index"

### Algorithm *spans2(X, n)*

$S \leftarrow$  new array of  $n$  integers

$A \leftarrow$  new empty stack

**for**  $i \leftarrow 0$  **to**  $n - 1$  **do**

**while**  $(\neg A.empty() \wedge X[A.top()] \leq X[i])$  **do**

$A.pop()$

**if**  $A.empty()$  **then**

$S[i] \leftarrow i + 1$

**else**

$S[i] \leftarrow i - A.top()$

$A.push(i)$

**return**  $S$

18

## Computing Spans with a Stack

□ We keep in a stack the indices of the elements visible when "looking back"

□ We scan the array from left to right

- Let  $i$  be the current index
- We pop indices from the stack until we find index  $j$  such that  $X[i] < X[j]$
- We set  $S[i] \leftarrow i - j$
- We push  $i$  onto the stack

19

## Linear Algorithm

- ◆ Each index of the array
  - Is pushed into the stack exactly one
  - Is popped from the stack at most once
- ◆ The statements in the while-loop are executed at most  $n$  times
- ◆ Algorithm *spans2* runs in  $O(n)$  time

### Algorithm *spans2(X, n)*

$S \leftarrow$  new array of  $n$  integers

$A \leftarrow$  new empty stack

**for**  $i \leftarrow 0$  **to**  $n - 1$  **do**

**while**  $(\neg A.empty() \wedge X[A.top()] \leq X[i])$  **do**

$A.pop()$

**if**  $A.empty()$  **then**

$S[i] \leftarrow i + 1$

**else**

$S[i] \leftarrow i - A.top()$

$A.push(i)$

**return**  $S$
